Raw Material Screening with GC-MS: Flavor Analysis of Malted Grain from Hot Steeped Malt

LECO Corporation; Saint Joseph, Michigan USA

Key Words: GC-MS, GC-TOFMS, Pegasus BT, HS-SPME, Raw Materials, Malted Barley

Introduction

The ability to screen raw ingredients early in the production process for a food or beverage is useful for quality control, and also for identifying process modifications or optimizations to achieve the desired characteristics of the product. For beer, malted barley is one of the primary ingredients and it is added early in the brewing process. It provides complex carbohydrates and sugars that are crucial for fermentation and it also imparts flavor, body, and color to the final product. The flavor contribution depends largely on the style of malt used. Base, caramel, and dark roasted malts are all common and each lends unique flavor notes and characteristics. Traditionally, a chew test of whole kernels has been used as a check for flavor and freshness. While this test provides insight and has the benefit of being very fast, it does not fully reflect the flavors that are extracted during the brewing process that would be anticipated in the final product. The American Society of Brewing Chemists has a published Method of Analysis, the "Hot Steep Malt Sensory Evaluation Method",^[1] to prepare malt extracts for sensory analysis that are more representative of the malt in the beer. Chemical analyses are good complements to traditional sensory analysis and here we aim to further investigate these types of samples with a non-targeted chemical analysis. Head space solid phase micro-extraction (HS-SPME) was used to collect the volatile and semi-volatile flavor analytes, and gas chromatography coupled to mass spectrometry (GC-MS) was used for subsequent analysis. A variety of malt extracts were prepared and analyzed yielding data that provided information on individual analytes differentiating these malt styles. Many of the observed analytes have known flavor and odor properties which can be connected with the sensory attributes of the malts.

Figure 1. Six malt extracts were compared. Representative Total Ion chromatograms (TIC) and pictures are shown for each and PCA of the TIC traces was performed.

Experimental

Six varieties of malted barley, listed in Table 1, were prepared for analysis based on the ASBC's "Hot Steep Malt Sensory Evaluation Method."¹¹ For this work, the method was scaled to 20% due to the reduced volume required for analytical analysis compared to sensory analysis. For each malt variety, 10 g of ground malt were added to 80 mL of 65 °C water in an insulated thermos and mixed with shaking. After 15 minutes of extraction, the contents were swirled and filtered, resulting in the malt extract/wort samples. As advised in the protocol, base malts were analyzed at 100%, specialty malts were mixed with base malt at 50%, and dark roasted specialty malts were mixed with base malt at 15%. For each sample, 5 mL of wort were pipet into a 20 mL glass vial with septum cap. The samples were incubated for 5 min at 35 °C and then extracted with a DVB/CAR/PDMS fiber (Supelco) for 10 min at the same temperature. Each sample was then analyzed by GC-MS with the Pegasus BT (LECO). All analytical data for a given sample was acquired within 4 h of filtration. Instrument conditions are listed in Table 2.

Table 1. Malted Barley Varieties

| Sample | Name | Malt Type | Inclusion Level | Lovibond |
|--------|--------------|----------------------|-----------------|----------|
| A | 2-Row | Base | 100 % | 1.8 |
| B | Aromatic | Specialty | 50 % | 20 |
| C | Caramel 20L | Specialty | 50 % | 20 |
| D | Caramel 120L | Specialty | 50 % | 120 |
| E | Chocolate | Dark Roast Specialty | 15 % | 350 |
| F | Black | Dark Roast Specialty | 15 % | 500 |

Table 2. GC-TOFMS (Pegasus BT) Conditions

| Gas Chromatograph | Agilent 7890 with LECO L-PAL 3 Autosampler |
|------------------------|---|
| Injection | SPME, 3 min desorption in 250 °C inlet |
| Carrier Gas | He @ 1.4 mL/min, Constant Flow |
| Column One | Stabilwax, 30 m x 0.25 mm i.d. x 0.25 µm coating (Restek) |
| Temperature Program | 3 min at 40 °C, ramped 10 °C/min to 250 °C, hold 1 min |
| Transfer Line | 250 °C with uncoated guard column |
| Mass Spectrometer | LECO Pegasus BT |
| Ion Source Temperature | 250 °C |
| Mass Range | 33-500 m/z |
| Acquisition Rate | 10 spectra/s |

Results and Discussion

Different malt styles are produced by altering the temperature and duration of kiln heating and/or roasting of the barley. These conditions drive various reactions, and alterations will yield a range of malt styles and impact the types and amounts of the reaction by-products produced. Both caramelization, the breakdown of sugars, and the Maillard reaction, the reaction of a reducing sugar with an amino acid, are anticipated and have by-products with important odor and flavor characteristics. The malt styles are categorized as base, specialty, or dark roast specialty with the darker roasted malts generally heated to higher temperatures for greater lengths of time. Extracts from six varieties of malted barley, shown in Figure 1 and described in Table 1, were analyzed and compared. These included a base malt, three specialty malts, and two dark roast specialty malts. Chromatograms for each of the extracts, shown in Figure 1, represent the aroma profiles of each sample. Some similarities and many differences are apparent between the samples and preliminary general characterization was done with Principle Component Analysis (PCA) of the TIC traces. The scores plot, where each sample is represented as a data point, is shown in Figure 1. The extracts from each malted barley variety distinctly cluster and the dark specialty roast samples have lower PC1 scores while the caramel malts have higher PC1 scores.

The general distinction of these samples can be further explored by looking at trends of individual analytes across the malt varieties. With this analytical technique, individual analytes are separated from each other both chromatographically and mathematically. Chromatographic coelution still frequently occurs with complex samples and many of these cases can be distinguished with mathematical deconvolution of the full mass range TOFMS data, as demonstrated in Figure 2. There are two apparent peaks in the TIC, but spectral patterns indicate the coelution of four analytes. By plotting masses unique to each, the peak shapes can be observed and integrated to provide peak areas and information on the relative trend across the samples. Pure spectral information for each analyte is also generated and when matched with commercially available libraries, provides tentative identification information from which odor characteristics can be determined. These four analytes, that were confounded in the TIC, have interesting odor characteristics and distinctly different trends that were observed because of deconvolution capabilities. 2(3H)-furanone, dihydro-5-pentyl is observed in all of the samples with only subtle differences between the malt styles. This analyte has sweet, buttery, coconut, creamy, waxy, and oily odor descriptors. Furanol has caramel, cotton candy, sweet, strawberry, and sugar odor descriptors and is observed at highest levels in the 120L caramel malt with varying levels in the other styles. 1H-pyrrole-2-carboxaldehyde and 4-ethyl-2-methoxy phenol were both observed at highest levels in the chocolate malt. The pyrrole has coffee and musty odor descriptors while the phenol has odor descriptors of

smoky, spicy, bacon, phenolic, and clove. The decrease in the levels in the black malt is potentially attributed to thermal breakdown as black malt is often heated to higher temperatures (above 260 °C), driving further reactions and also surpassing the boiling point of some of these compounds (217-219 °C and 234-236 °C for the pyrrole and phenol compounds, respectively).

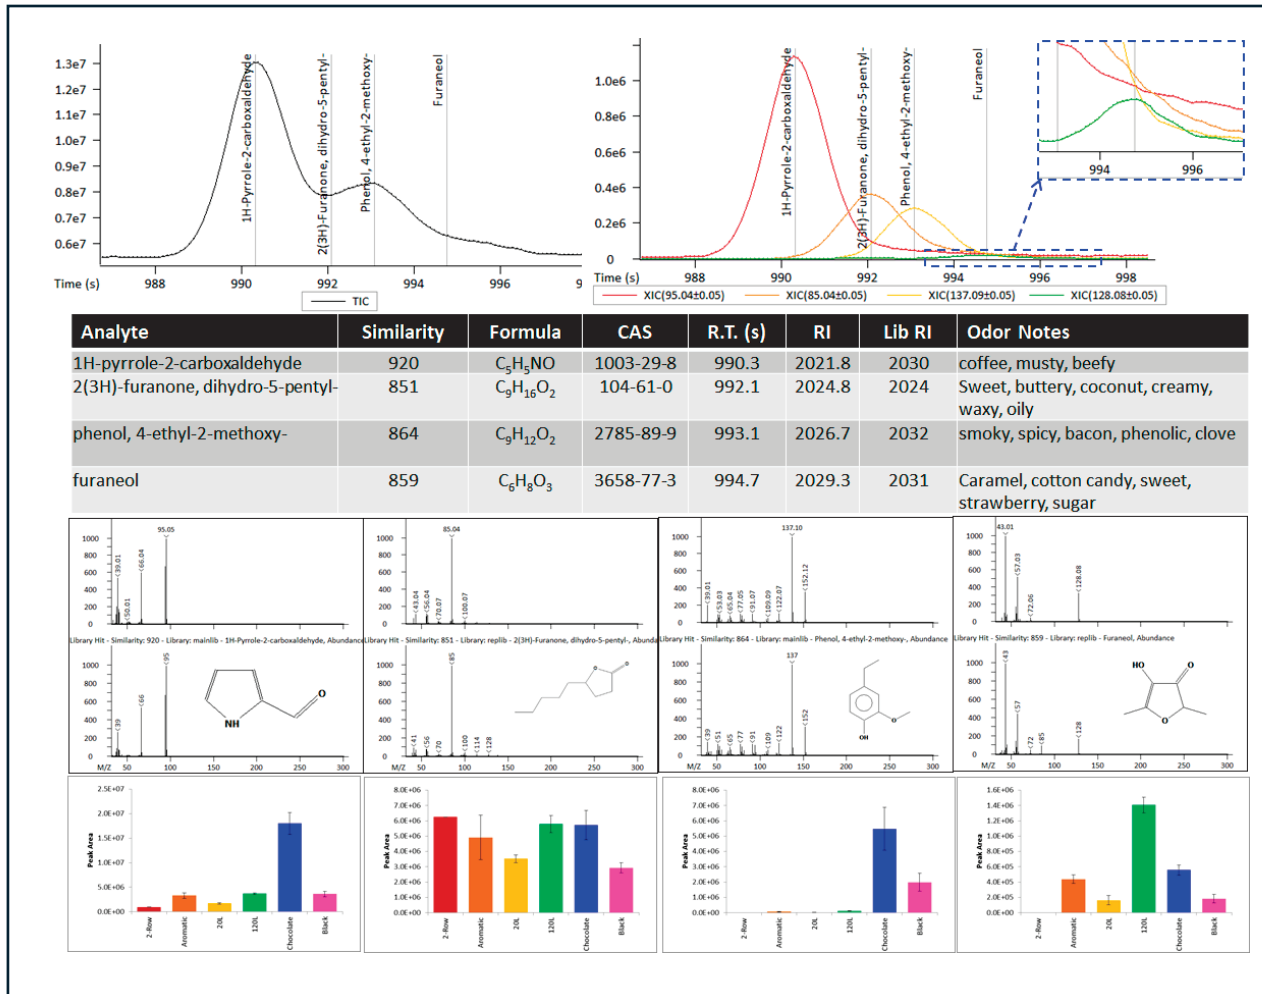

Figure 2. Deconvolution separates four individual analytes that appear as two peaks in the TIC. These analytes are present at different levels in each sample, likely contributing to some of the flavor differences related to malt variety used.

Many other individual analytes were observed and information for nearly 200 compounds was compiled in Figure 3 and Appendix A. These specific analytes were identified based on mass spectral similarity (>800) compared to the NIST 2017 database and retention index matching (library vs observed < 40 RI units). A wide range of analyte types were observed, including: alcohols, aldehydes, ketones, hydrocarbons, aromatics, esters, furans, pyranones, pyrazines, pyridines, pyrroles, sulfides, thiophenes, etc. Information on these tentative analyte identifications is compiled in Appendix A. Relative peak area trends were also determined across the malted barley varieties, demonstrated in the heat map, with several distinct trends observed.

A collection of specific analytes are highlighted in Figure 4 with additional details compiled. These analytes may be of particular interest because of their known relationships to malting and/or brewing. Dimethyl sulfide (DMS) is produced during germination and the early stages of kilning, and is an important odor compound with sulfury or corn descriptors. As a volatile compound, it can be driven off during the higher temperature kilning or roasting of specialty and dark specialty roasted malts. As expected, DMS was observed at highest levels in the base malt and at lower levels in the specialty and dark roast specialty malts. Methional is also an important odor compound related to beer and has potato odor characteristics. This is a breakdown product of the amino acid, methionine, and is often a target of routine screening. We observe methional at highest levels in the Aromatic and Caramel 120L malts. By-products of caramelization and the Maillard reaction are also anticipated and nitrogen-containing rings, like 2-6-dimethyl pyrazine, are potential Maillard reaction products while maltol is likely a caramelization product. The trends of these specific analytes and other similar analytes across the 120L, Chocolate, and Black malts may shed light on the types of reactions occurring for each type of malt.

Figure 3. Peak area trends by malt variety.

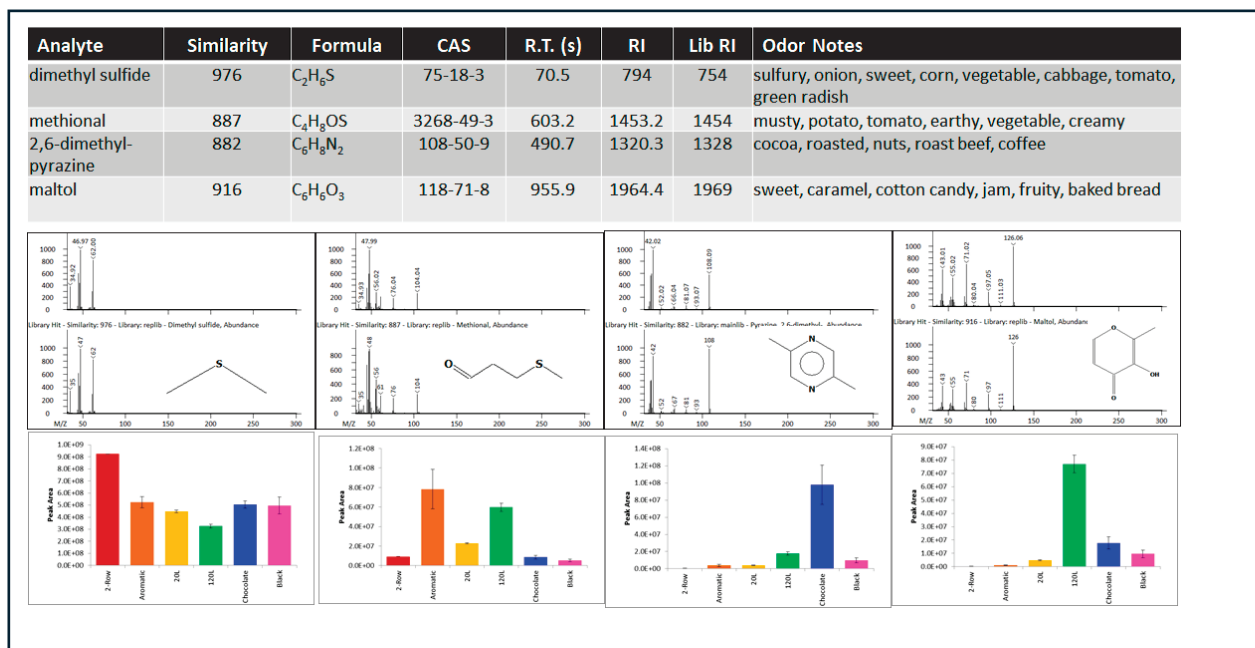

Figure 4. Representative analytes with distinct trends related to the malt varieties are shown.

Conclusion

In this work, we demonstrate an analytical method for analyzing malt extracts, prepared by the ASBC's "Hot Steep Malt Sensory Evaluation Method" intended for sensory analysis. The malt extracts were sampled with HS-SPME and analyzed with GC-MS. This analytical approach can provide good complementary data on individual analytes and help uncover more about your sample. Hundreds of analytes were identified and compared, with many malt specific trends observed. Many caramelization and Maillard reaction products were observed at elevated levels in the samples roasted at higher temperatures.
